DNA data storage - A new storage medium

- **Principle** – [WRITING] Encode binary data into 4-base sequences following the DNA structure, transfer this data into synthetic DNA molecules. [READING] Amplify encoded sequences of interest and get several reads of them with a sequencing device. Reads are then processed and decoded back to binary data
- **Constraints** – i) Biological DNA synthesis and sequencing are imperfect and introduce errors. ii) devices have structural DNA requirements when generating 4-base sequences
- **Vulnerabilities** – This chain is notably vulnerable to: theft or cloning of molecules; spying attacks on the sequencing or synthesis devices; DDoS attack by adding fake DNA sequence to confuse sequencing

Encoding solution to ensure data confidentiality in the entire DNA data storage channel

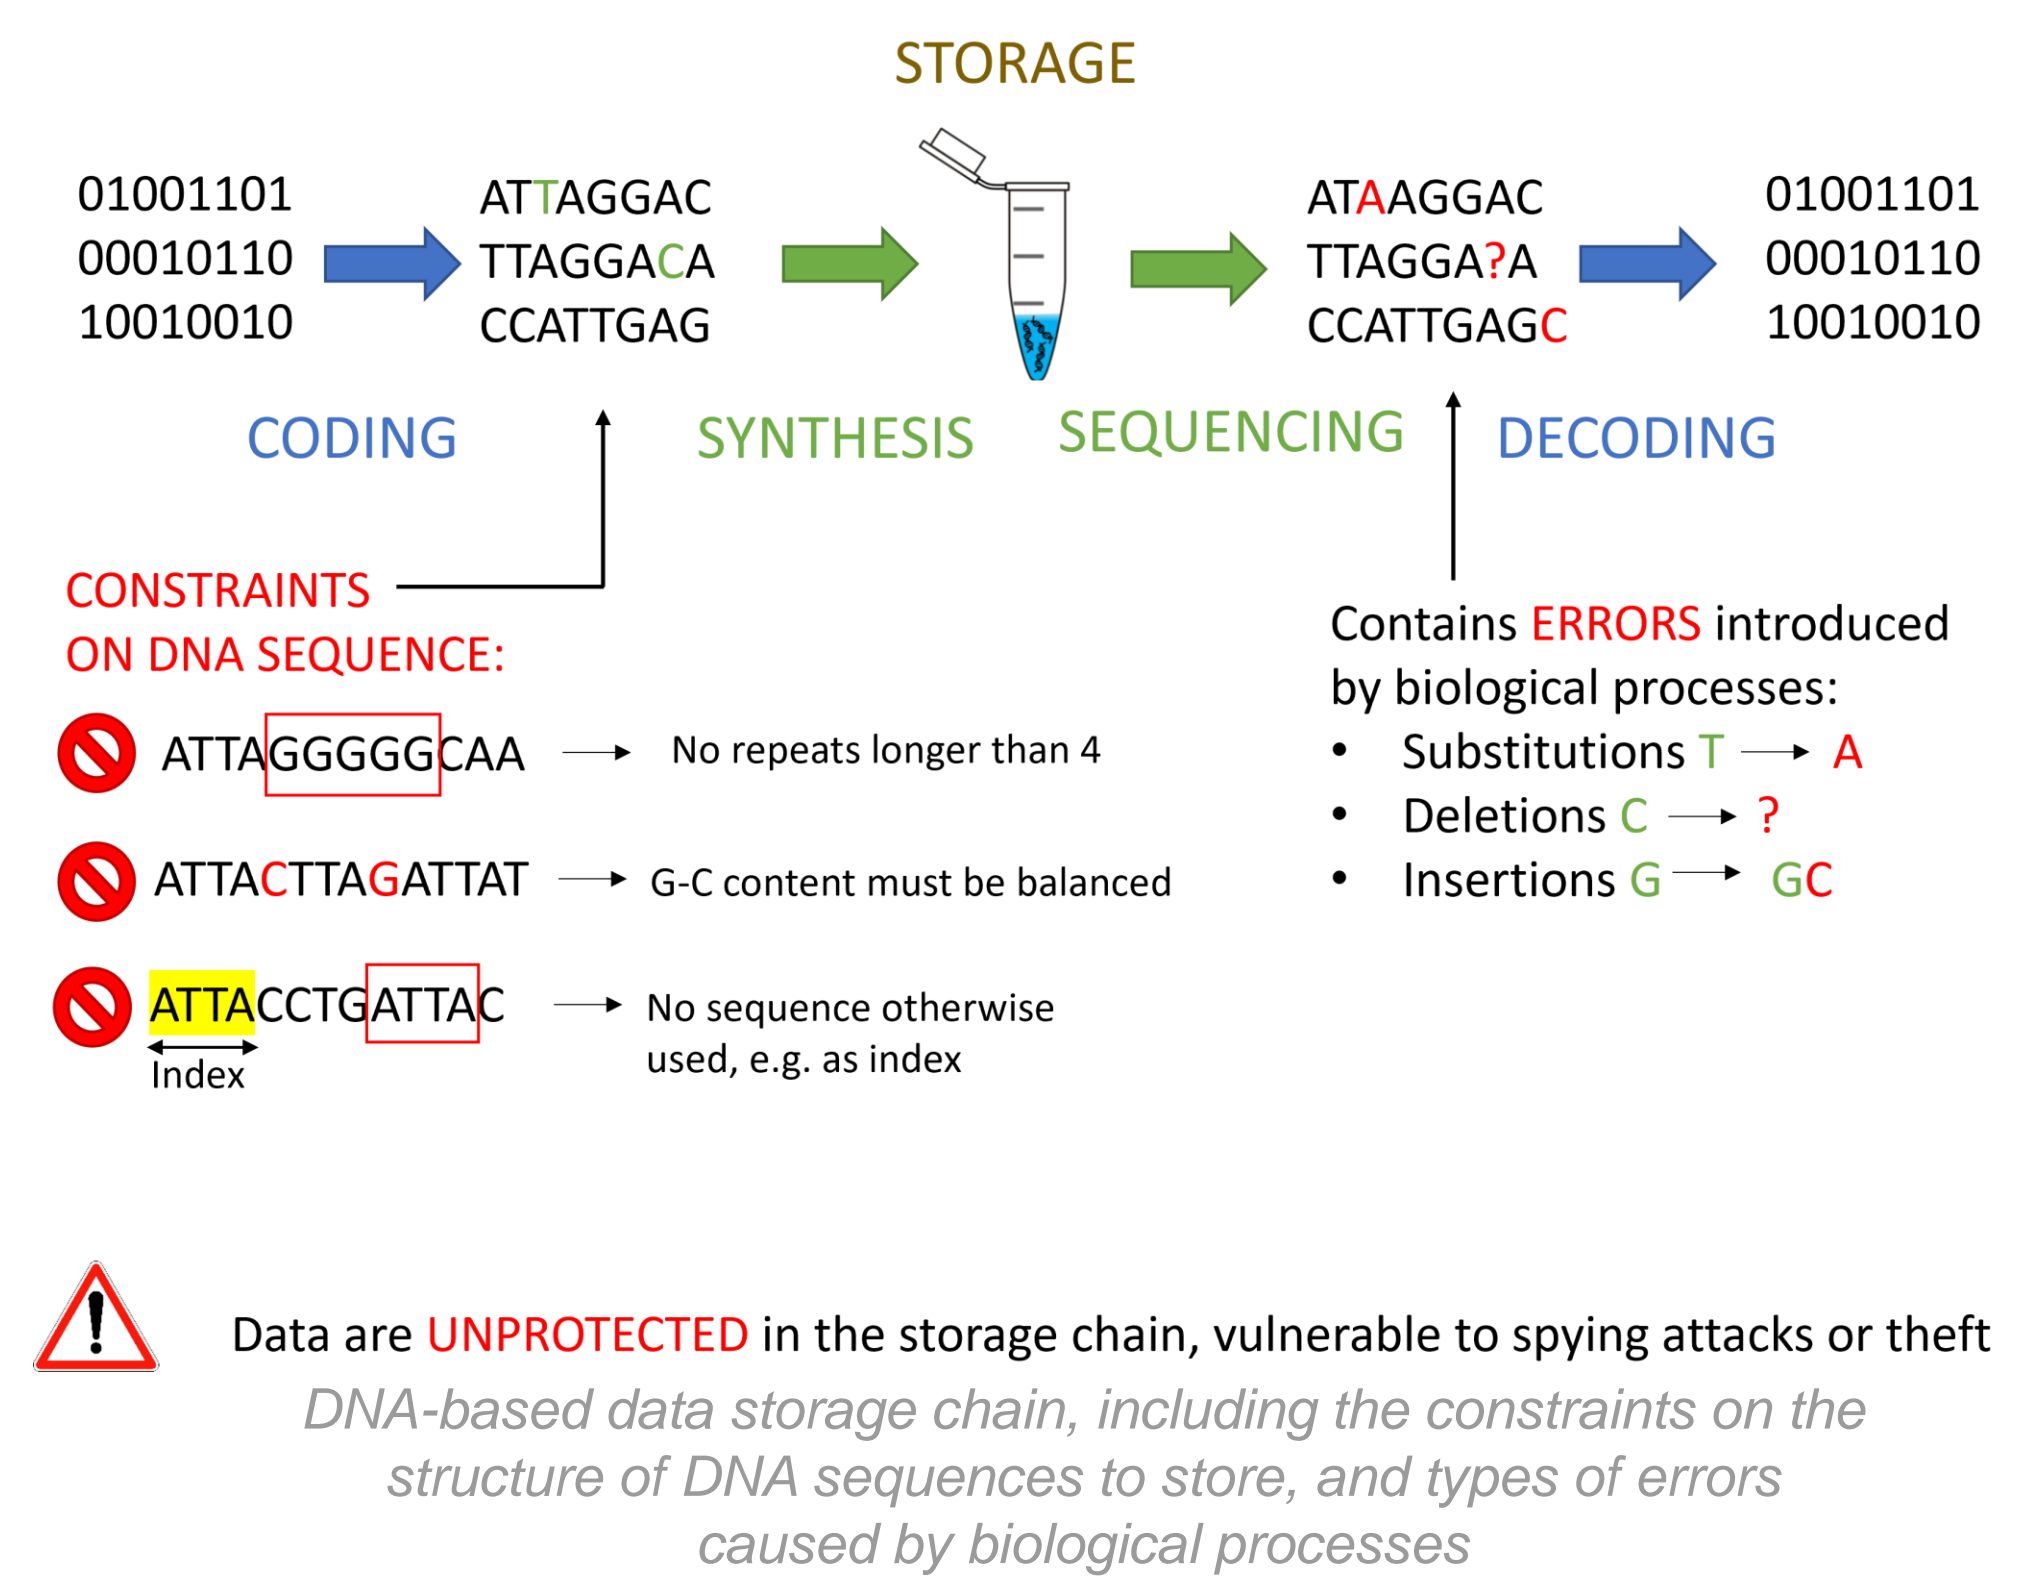

Dynamic information encoding into bases. In a block of N bases, each base X_i encodes two bits: b_{2i-1} and b_{2i} , except X_N , which encodes either b_{2N-1} only, or b_{2N-1} and b_{2N}

Experimental results

- **Simulation** of the biological processes using the simulator from [3]
- **Results:** no homopolymers longer than N , G-C content of 43-57%, data recovery without errors. For $N=4$, information rate of 1,875 bits per base.

Motivation - Considering the security of a promising storage medium

- **Context** – Actual storage technologies (flash memory, hard drives, magnetic tapes,..) are outpaced by the exponential rise of digital data production [1]
- **Advantages of DNA storage [2]** – Density of 10^{21} bytes in one gram (10^6 times more compact than hard disks), durability for centuries, energy cost close to zero (molecules kept at room temperature with no maintenance)
- **Motivation** – Introducing security to ensure the confidentiality of the data stored into DNA molecules

Data are UNPROTECTED in the storage chain, vulnerable to spying attacks or theft DNA-based data storage chain, including the constraints on the structure of DNA sequences to store, and types of errors caused by biological processes

Dynamic encoding - a solution for confidentiality

- **Challenge** - Ensure confidentiality under biological constraints while approaching the ideal rate of 2 bits of information per base
- **Solution** – A three step coding process that includes encryption, dynamic data encoding and error-correction code
 - **Step 1:** Encryption with AES-256 to ensure confidentiality and to regulate the G-C base rate and homopolymers
 - **Step 2:** Dynamic encoding to manage unwanted base patterns; encoding based on the addition or not of one bit of data every N bases to avoid homopolymers longer than N
 - **Step 3:** Non-binary LDPC error-correction code to correct any base substitutions, deletions or insertions

G-C content for $N=4$ for 1000 DNA sequences after encoding

Information rate (bits per base) depending on N , the maximal homopolymer size

Conclusion and future work

- **Confidentiality** in the entire storage chain that takes into account **biological constraints**
- Encoding solution **independent** from encryption algorithm and error-correction code, **adaptable** to the size of unwanted patterns
- Extend the approach to other synthesis and sequencing technologies
