Bitcoin: A Peer-to-Peer Electronic Cash System

Satoshi Nakamoto
satoshin@gmx.com
www.bitcoin.org

Abstract. A purely peer-to-peer version of electronic cash would allow online payments to be sent directly from one party to another without going through a financial institution. Digital signatures provide part of the solution, but the main benefits are lost if a trusted third party is still required to prevent double-spending. We propose a solution to the double-spending problem using a peer-to-peer network. The network timestamps transactions by hashing them into an ongoing chain of hash-based proof-of-work, forming a record that cannot be changed without redoing the proof-of-work. The longest chain not only serves as proof of the sequence of events witnessed, but proof that it came from the largest pool of CPU power. As

P vs NP

$$7 * 13 = ?$$

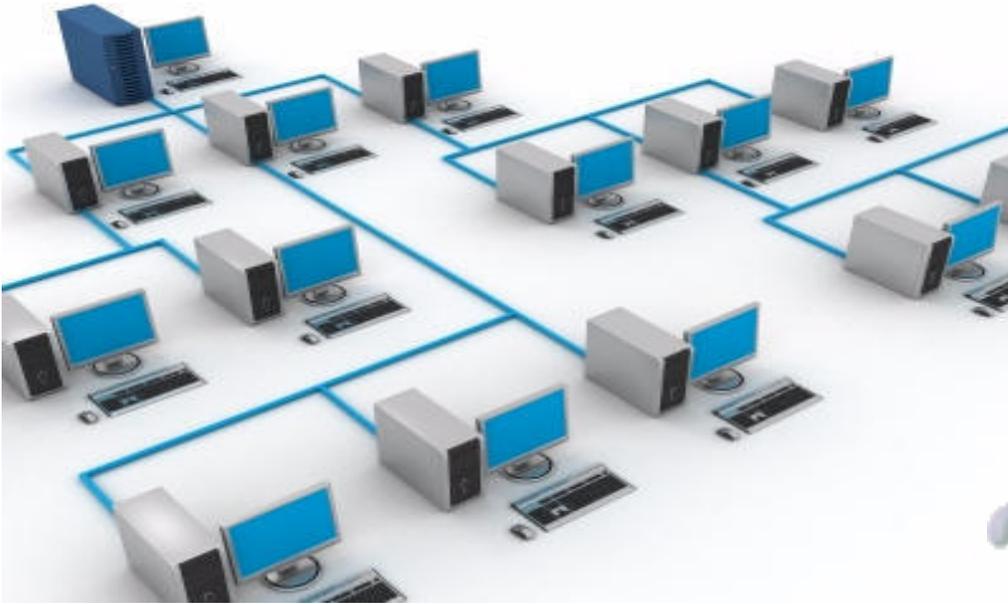

$$? * ? = 91$$

Asynchronous vs Synchronous

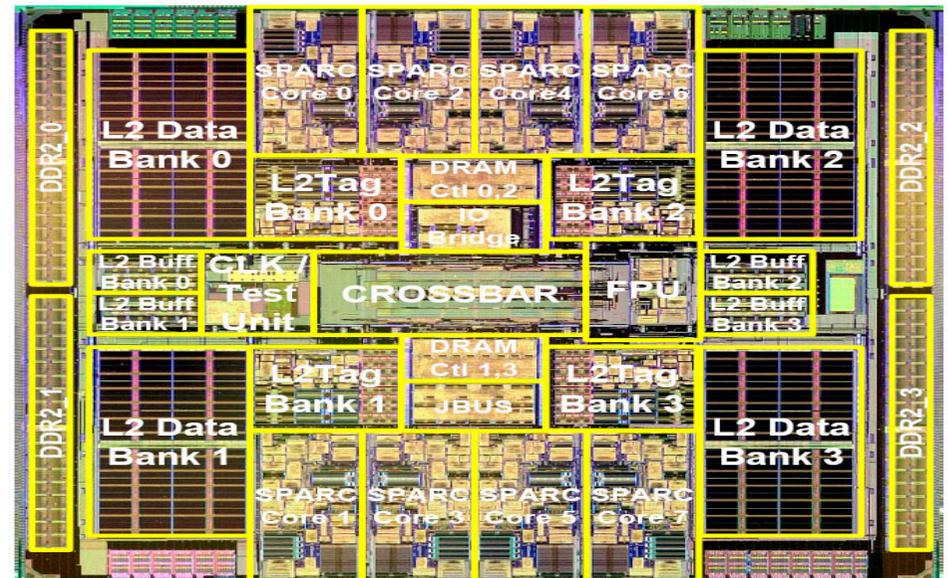

Is payment an asynchronous problem?

- « To understand a distributed computing problem: bring it to shared memory » T. Lannister

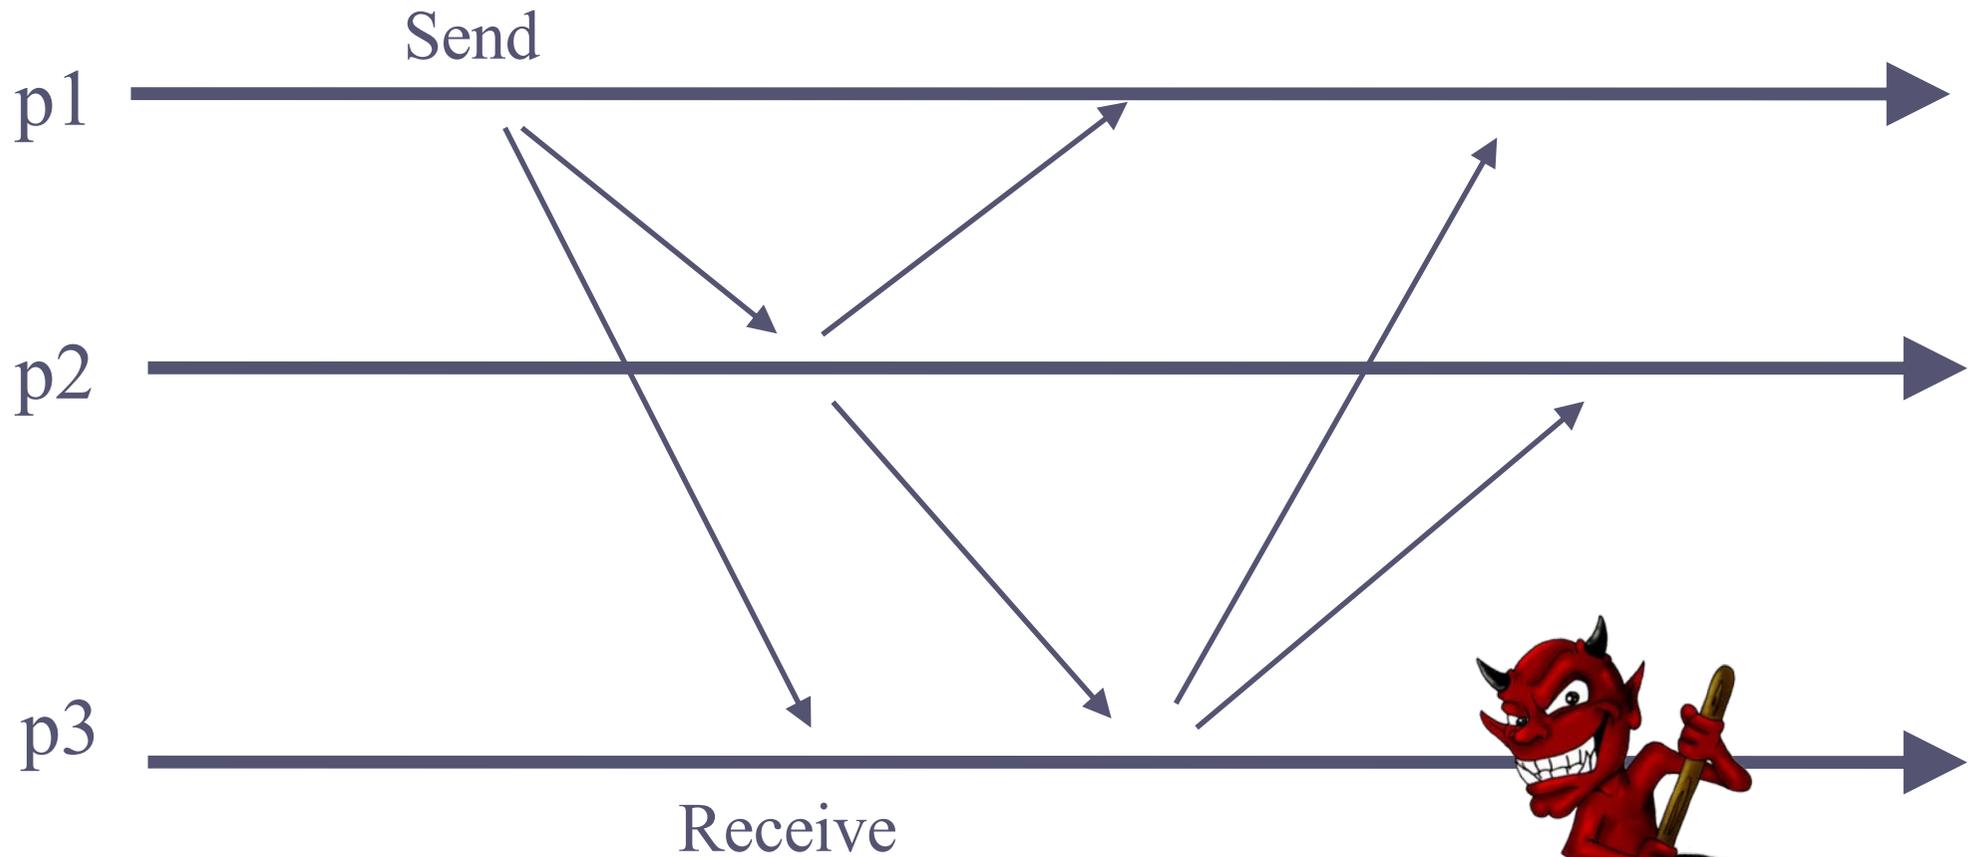

The infinitely big

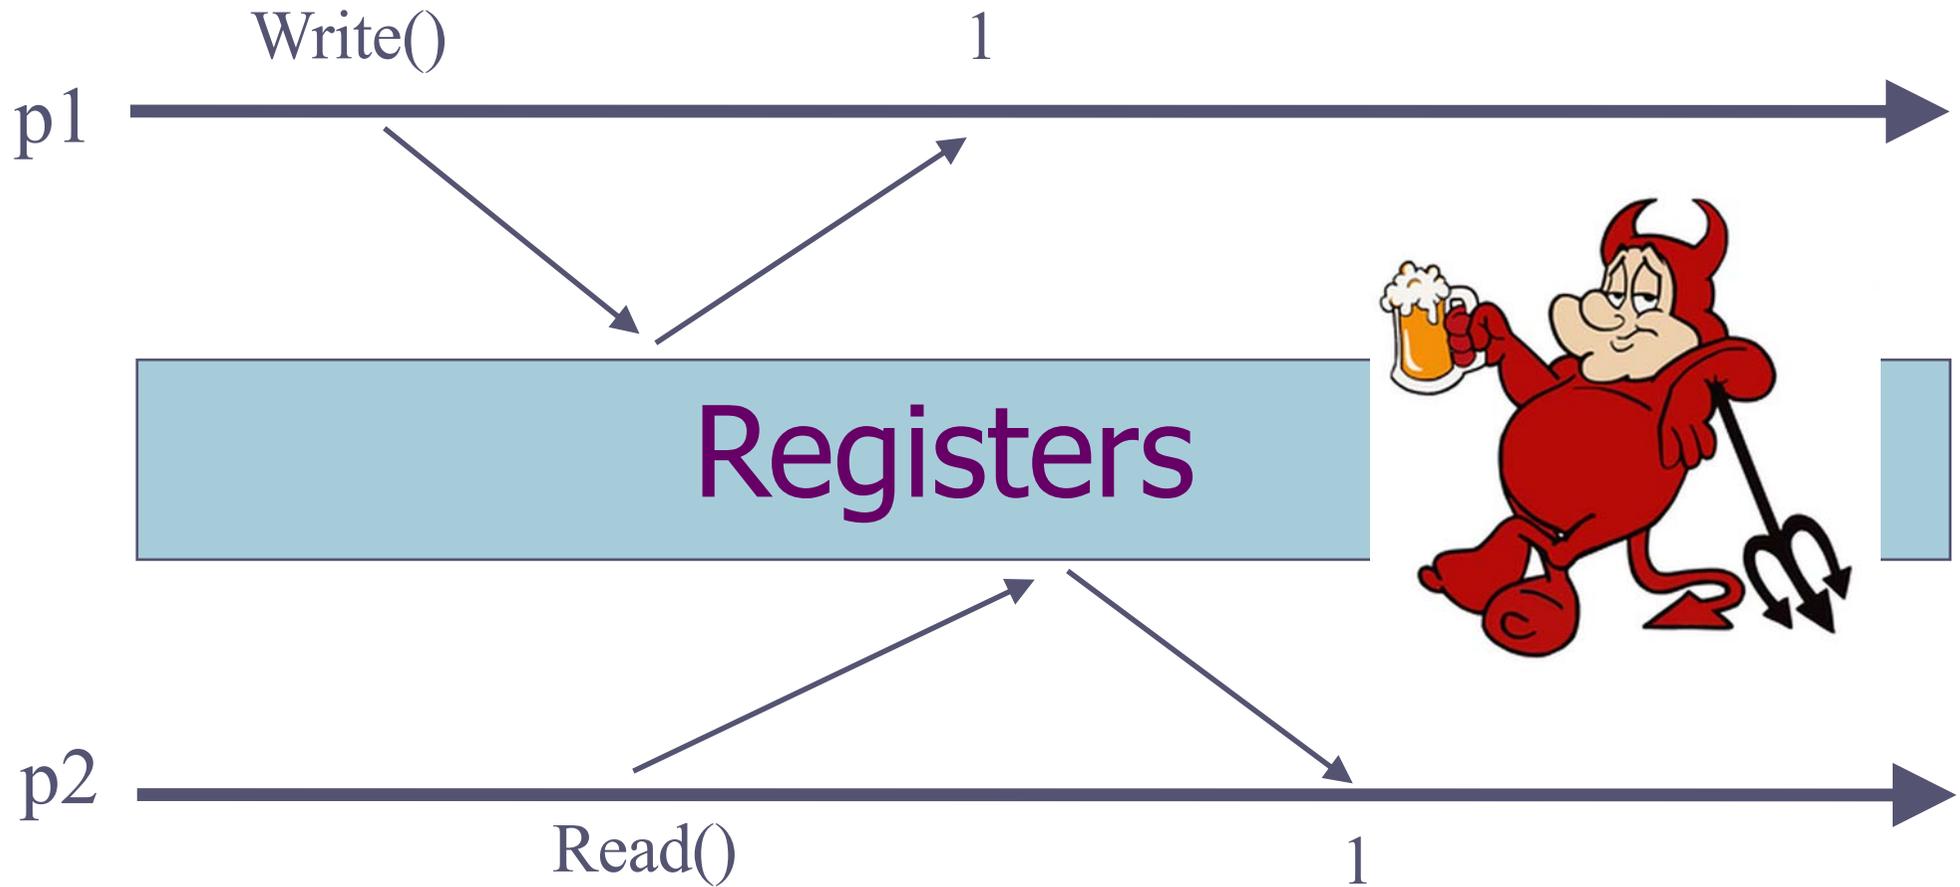

The infinitely small

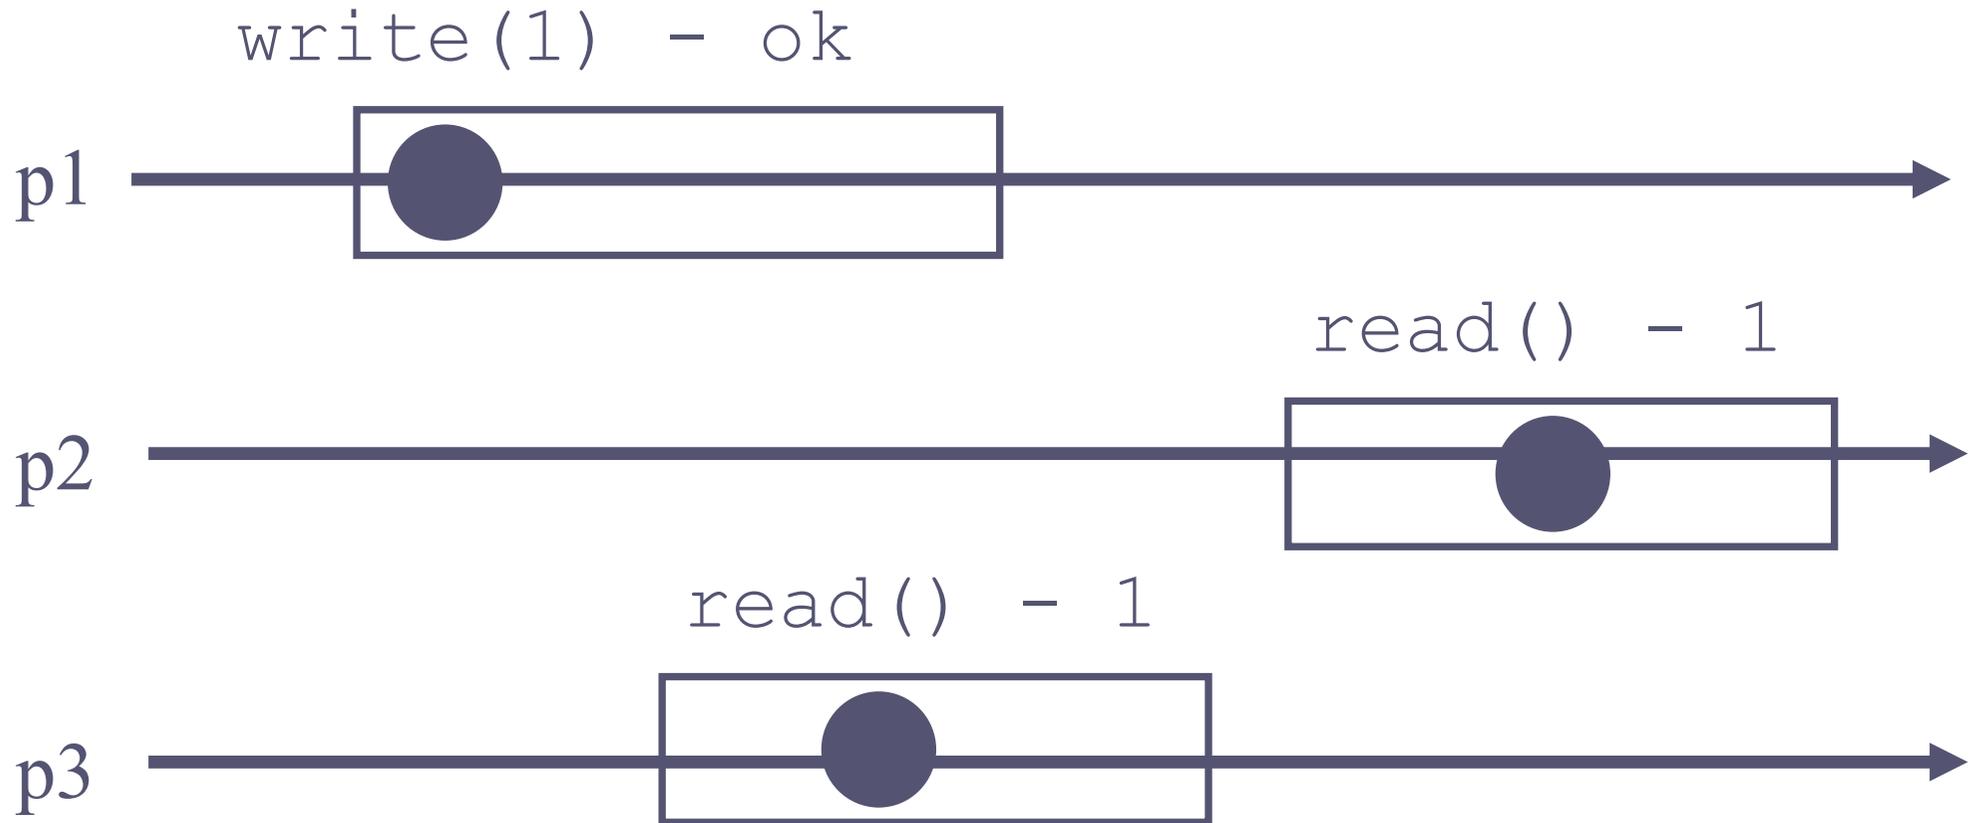

Message Passing

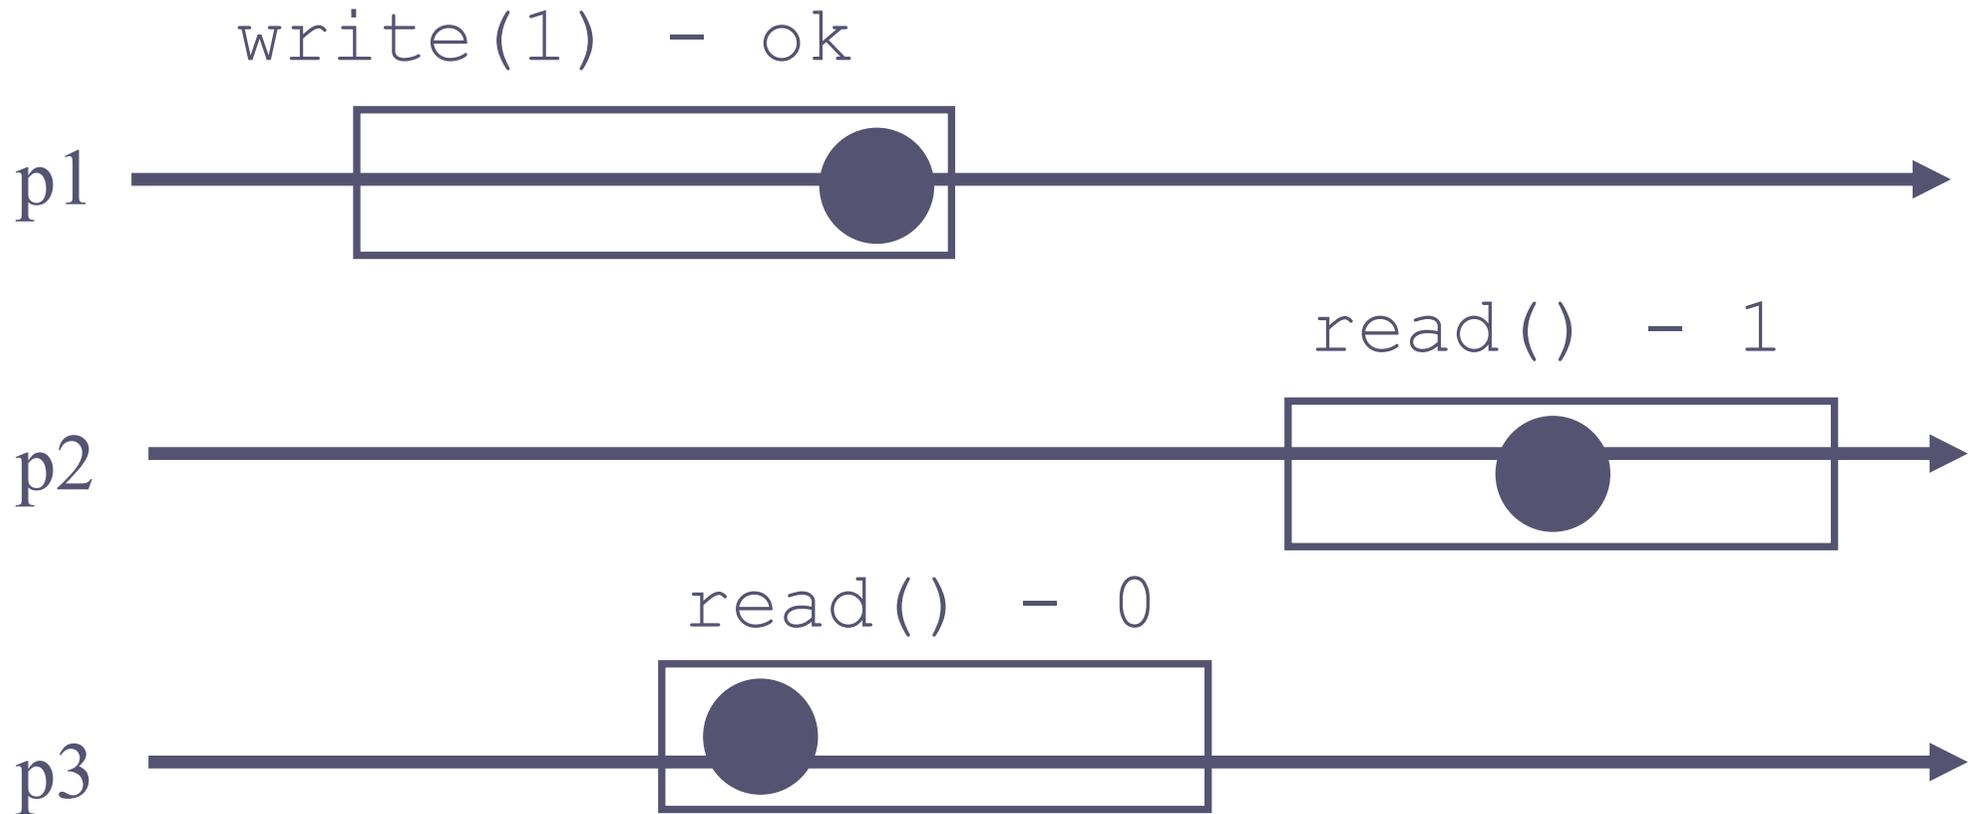

Shared Memory

Atomic Shared Memory

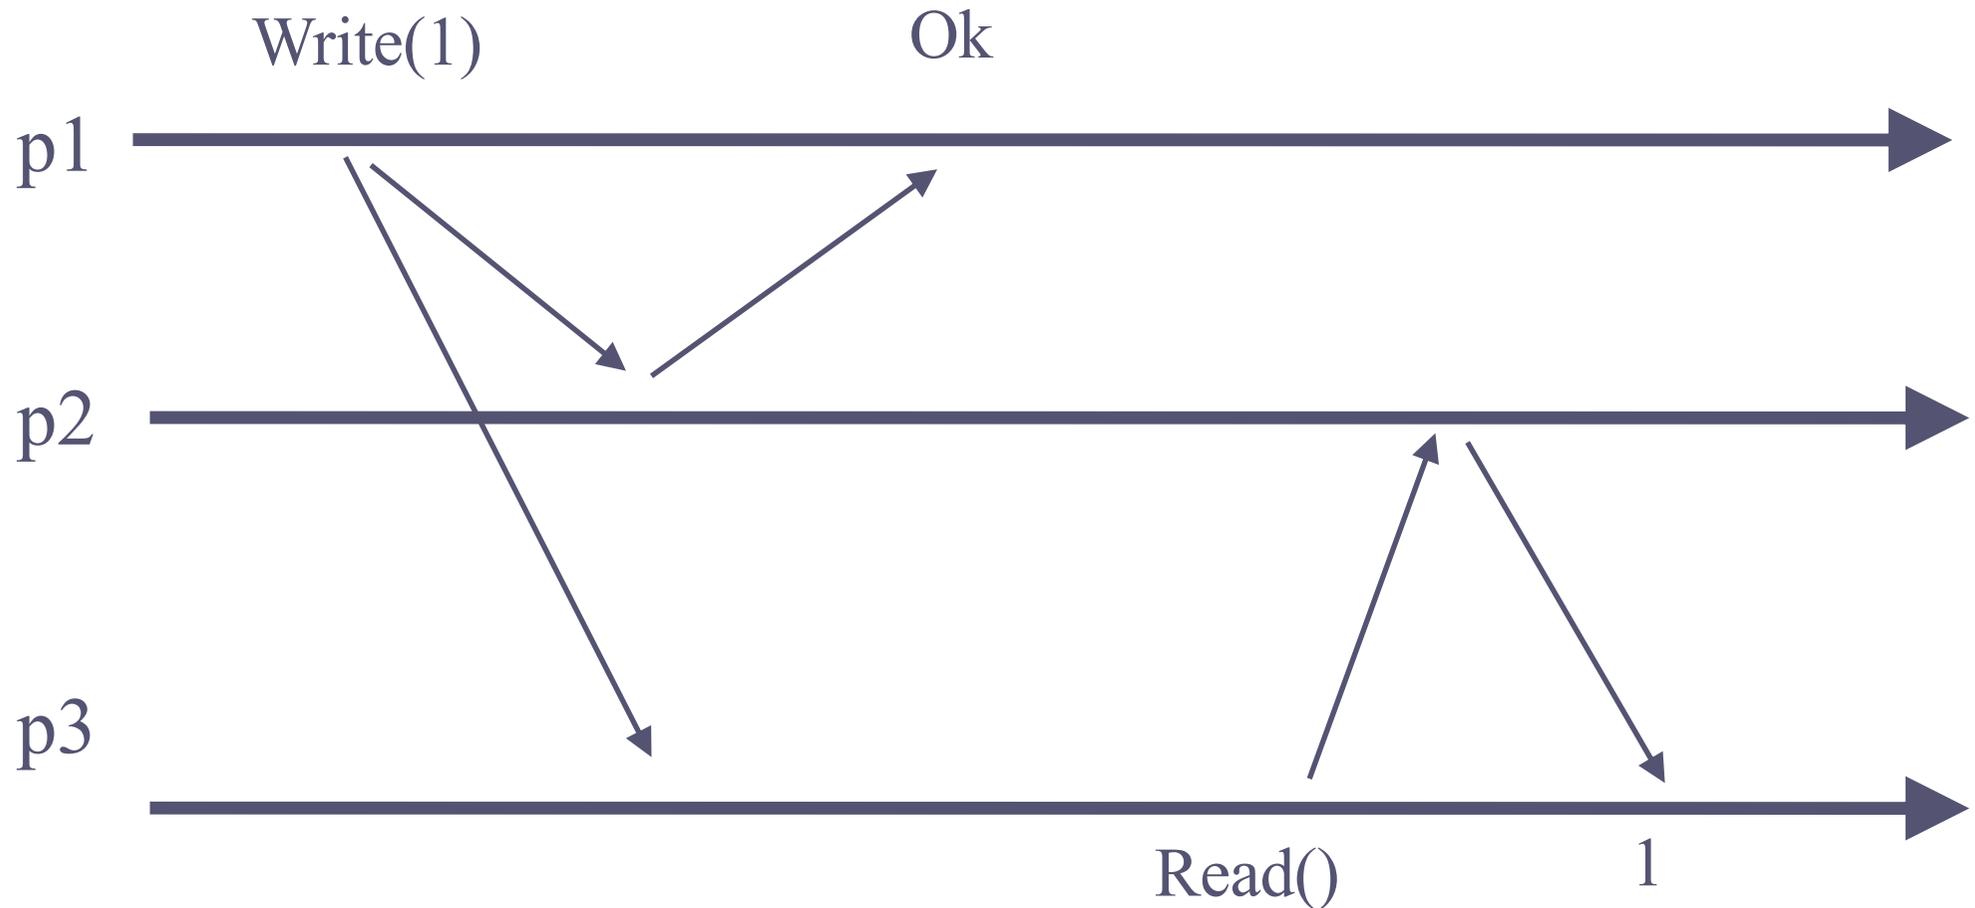

Atomic Shared Memory

Non-Atomic Shared Memory

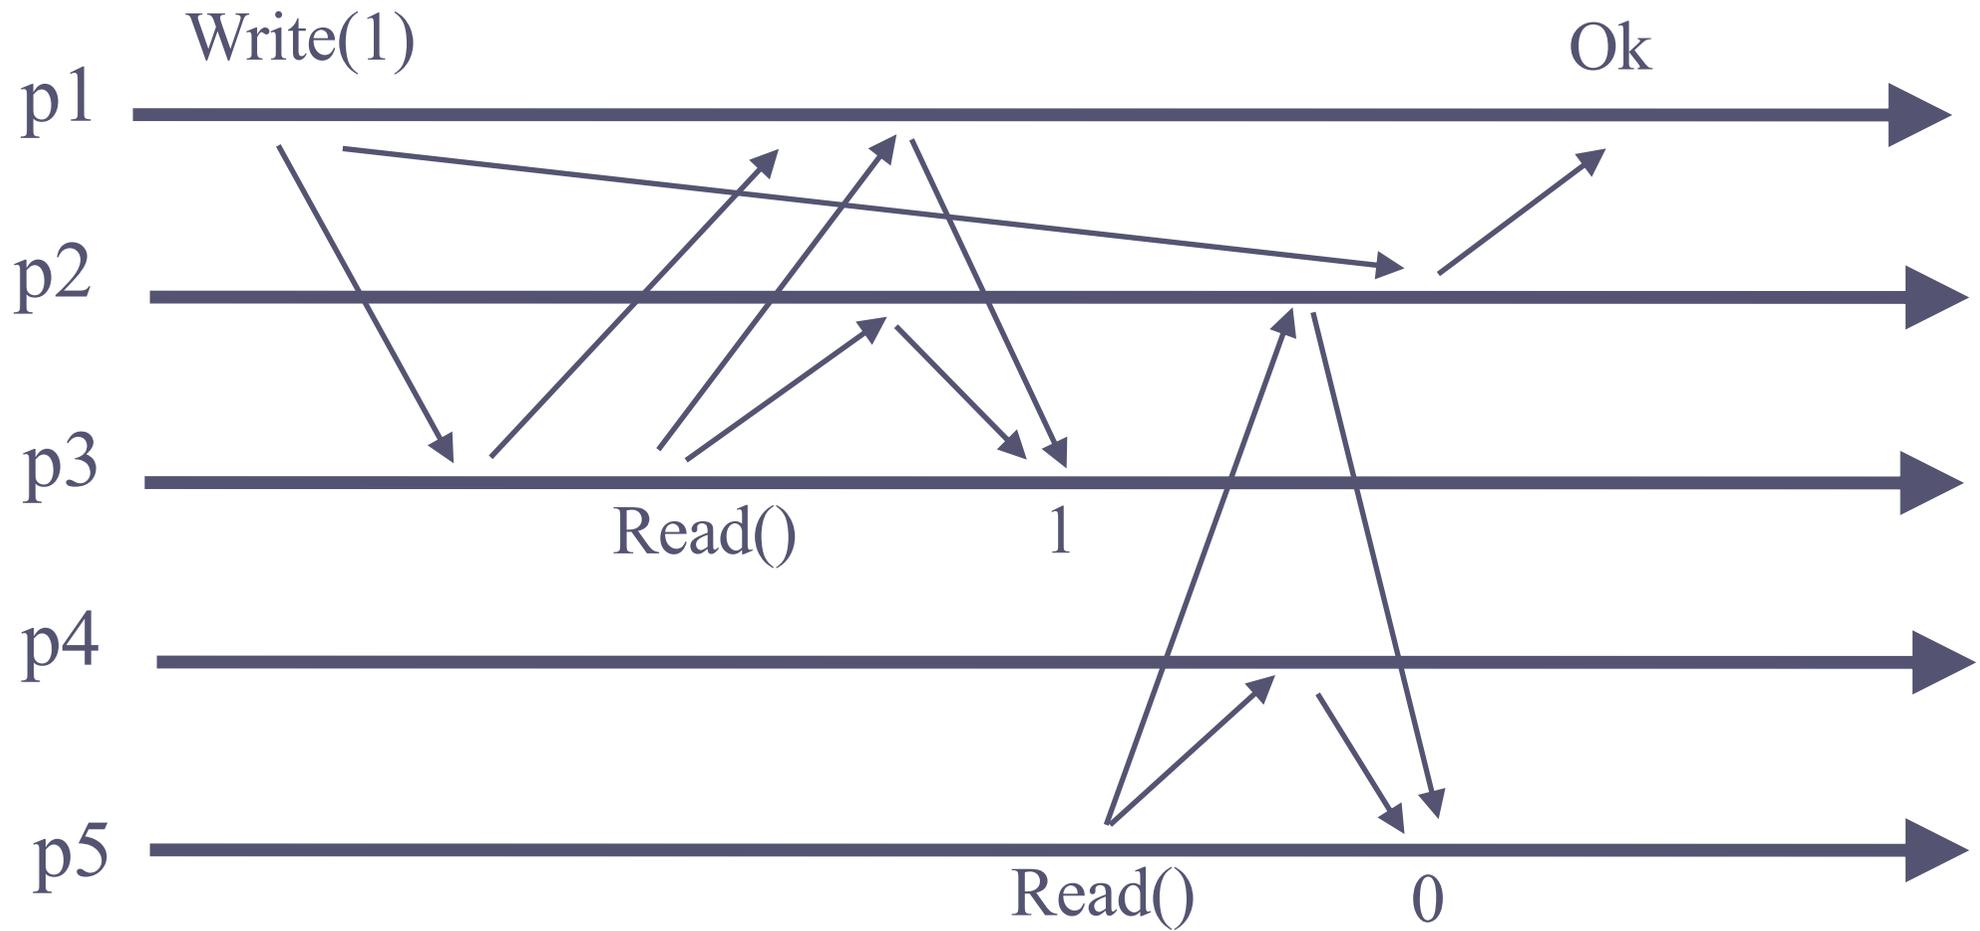

Message Passing \Leftrightarrow Shared Memory

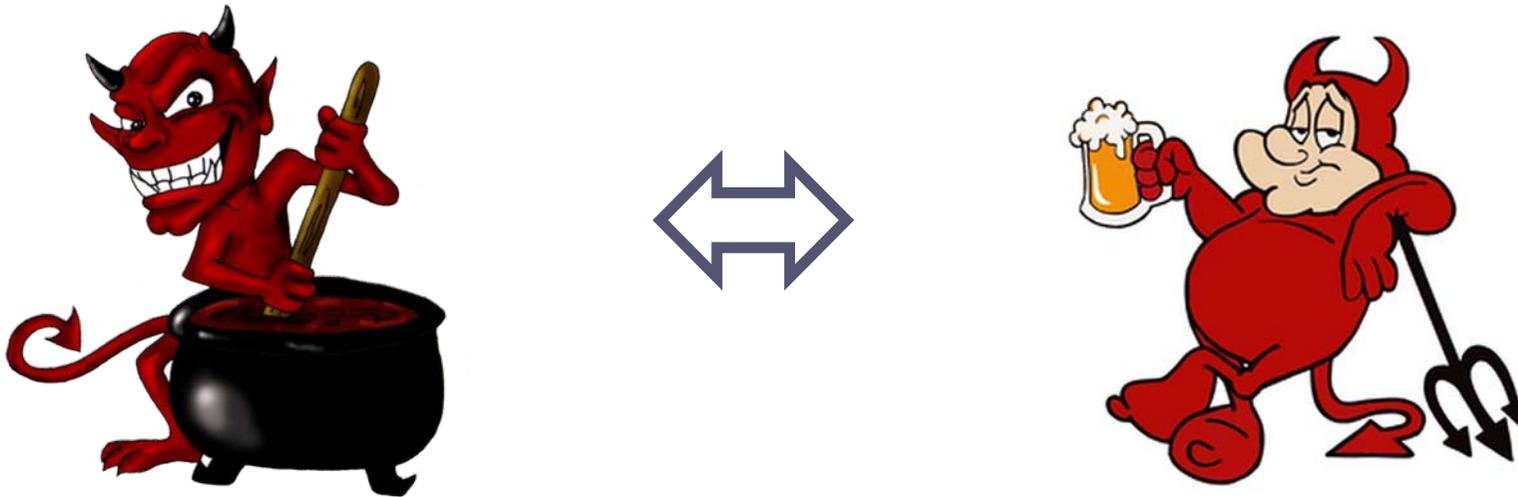

Quorums

Message Passing \Leftrightarrow Shared Memory

Message Passing \Leftrightarrow Shared Memory Modulo Quorums

☞ « Optimization is the source of all evil » D. Knuth

Is payment an asynchronous problem?

Payment Object

- Atomicity
- Wait-freedom

Counter: Specification

- A *counter* has two operations *inc()* and *read()*; it maintains an integer *x* *init to 0*
- *read()*:
 - return(*x*)
- *inc()*:
 - $x := x + 1;$
 - return(ok)

Counter: Algorithm

- The processes share an array of registers $\text{Reg}[1, \dots, N]$
- *inc()*:
 - $\text{Reg}[i].\text{write}(\text{Reg}[i].\text{read}() + 1);$
 - $\text{return}(\text{ok})$
- *read()*:
 - $\text{sum} := 0;$
 - for $j = 1$ to N do
 - $\text{sum} := \text{sum} + \text{Reg}[j].\text{read}();$
 - $\text{return}(\text{sum})$

Counter*: Specification

- *Counter** has, in addition, operation *dec()*
- *dec()*:
 - if $x > 0$ then $x := x - 1$; return(ok)
 - else return(no)

Can we implement Counter*
asynchronously?

Consensus

Agreement on a single value among multiple

Safety: No two processes must choose different values.

The chosen value must have been proposed by a process.

Liveness: Each process must eventually choose a value.

2-Consensus with Counter*

- Registers R0 and R1 and Counter* C - initialized to 1
- Process pI:
 - propose(vI)
 - RI.write(vI)
 - res := C.dec()
 - if(res = ok) then
 - ✓ return(vI)
 - ✓ else return(R{1-I}.read())

Impossibility [FLP85,LA87]

- ***Theorem:*** no *asynchronous* algorithm implements *consensus* among two processes using *registers*

- ***Corollary:*** no asynchronous algorithm implements Counter* among two processes using *registers*

The **consensus number** of an object is the maximum number of processes that can solve consensus with it

- ☛ **(2) The main question**
- ☛ **(3) The bitcoin problem/object**
- ☛ **(4) Back to Marrakech**
- ☛ **(5) The main message**

Payment Object (PO): Specification

- ☛ $\text{Pay}(a,b,x)$: transfer amount x from a to b if $a > x$
(return ok; else return no)
- ☛ **Important.** Only the owner of a invokes $\text{Pay}(a,*,*)$
- **Questions:**
 - - can PO be implemented asynchronously?
 - - what is the consensus number of PO?

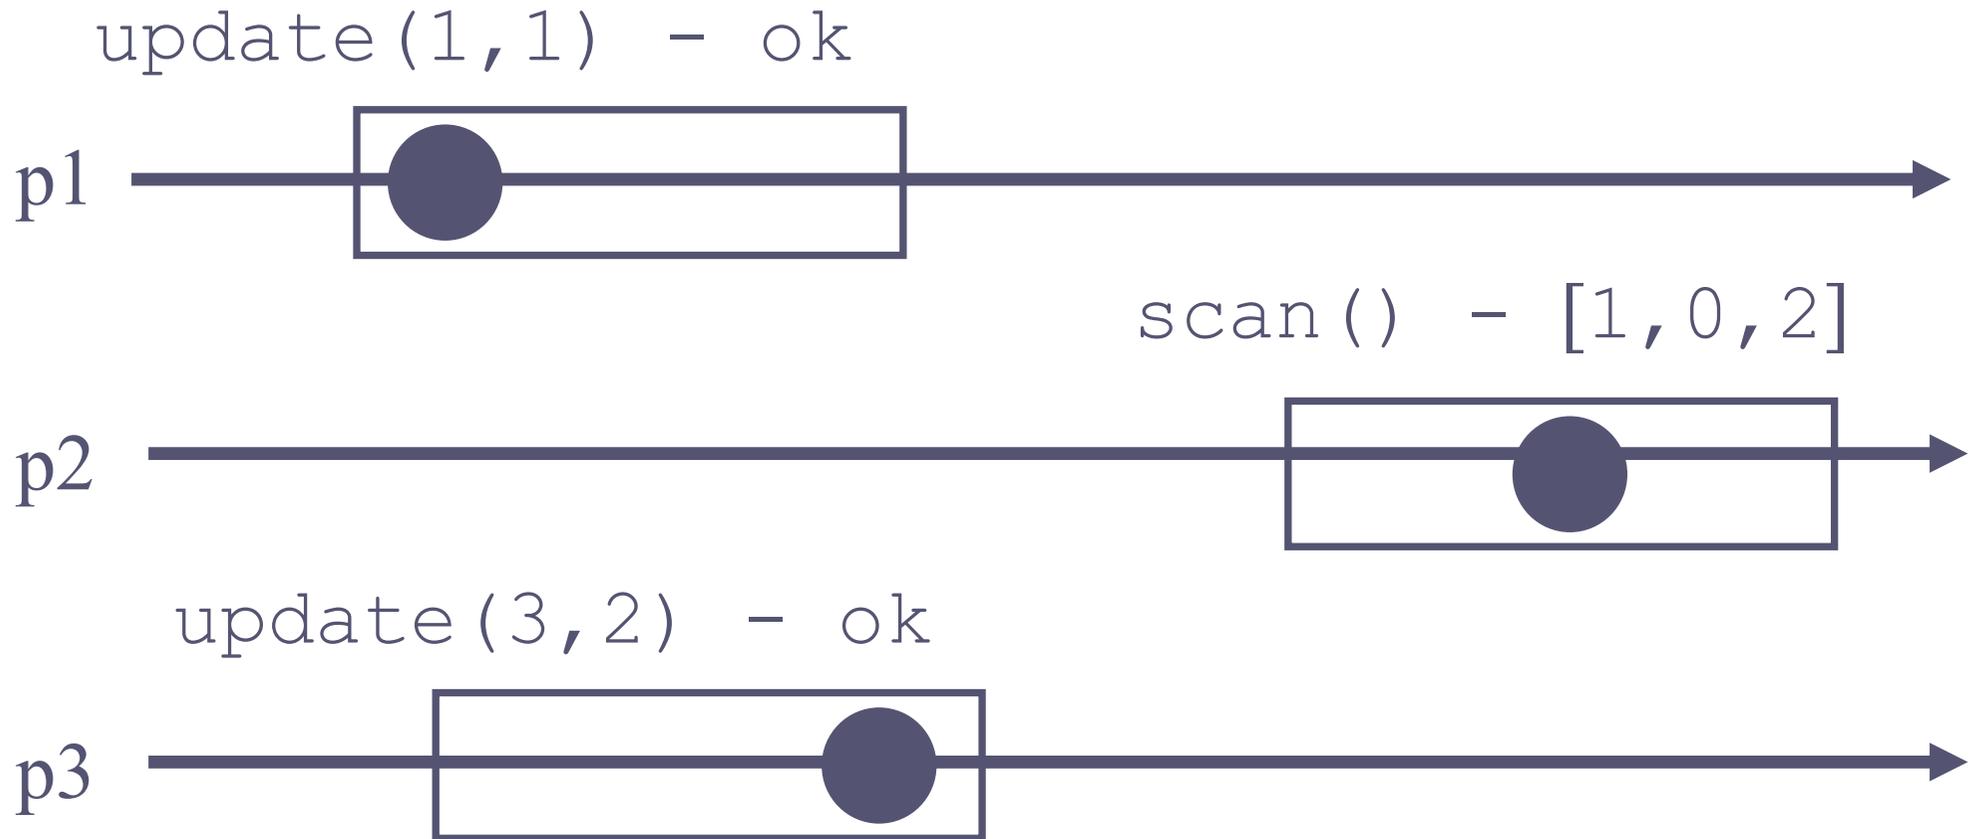

Snapshot: Specification

- A *snapshot* has operations *update()* and *scan()*; it maintains an array x of size N
- *scan()*:
 - return(x)
- *update(i, v)*:
 - $x[i] := v$;
 - return(ok)

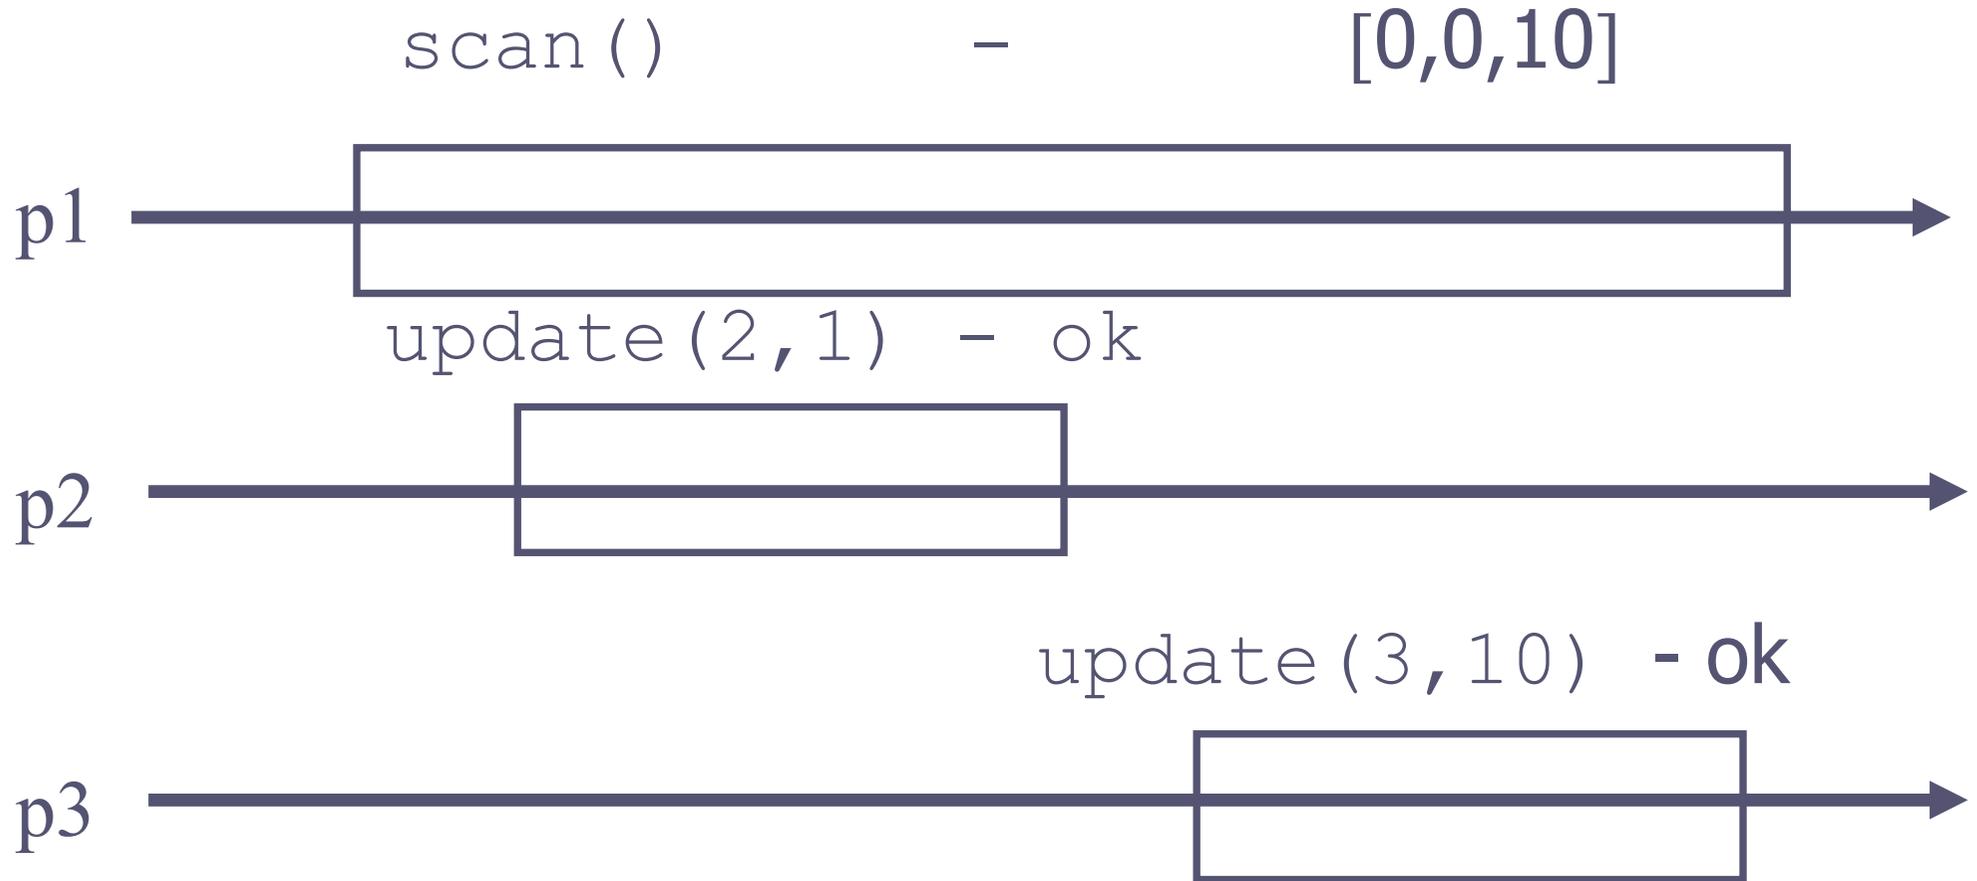

Algorithm?

- The processes share one array of N registers
Reg[1,...,N]
- *scan()*:
 - for j = 1 to N do
 - x[j] := Reg[j].read();
 - return(x)
- *update(i,v)*:
 - Reg[i].write(v); return(ok)

Atomicity?

Atomicity?

Key idea for atomicity

- To *scan*, a process keeps reading the entire snapshot (i.e., *collecting*), until two arrays are the same

Key idea for wait-freedom

- To update, scan then write the value and the scan
- To *scan*, a process keeps collecting and returns a collect if it did not change, or some collect returned by a concurrent *scan*

The Payment Object: Algorithm

- Every process stores the sequence of its outgoing payments in its snapshot location
- To *pay*, the process scans, computes its current balance: if bigger than the transfer, updates and returns ok, otherwise returns no
- To *read*, scan and return the current balance

PO can be implemented asynchronously

Consensus number of PO is 1

Consensus number of PO(k) is k
