Fick's law: $J_i = D_i \nabla u_i$ for some $D_i > 0$. This leads to a system of decoupled diffusion equations. Fick's law is not always valid and in general J_i may depend on $\nabla u_1, \dots, \nabla u_n$ in multicomponent systems.

イロト イロト イヨト イヨト

In general,

$$\forall 1 \leq i \leq n, \quad J_i = \sum_{j=1}^n A_{ij}(u) \nabla u_j, \tag{1}$$

where $A_{ij} : \mathbb{R}^n \to \mathbb{R}$ is a smooth function for all $1 \leq i, j \leq n$.

イロト イヨト イヨト イヨト

In general,

$$\forall 1 \leq i \leq n, \quad J_i = \sum_{j=1}^n A_{ij}(u) \nabla u_j, \tag{1}$$

where $A_{ij} : \mathbb{R}^n \to \mathbb{R}$ is a smooth function for all $1 \leq i, j \leq n$.

Equations (1) can be rewritten in a more condensed form using the notation

$$u = (u_1, \cdots, u_n), \quad J = (J_1, \cdots, J_n)$$

as

 $J = A(u)\nabla u$

where for all $u \in \mathbb{R}^n$, $A(u) = (A_{ij}(u))_{1 \le i,j \le n} \in \mathbb{R}^{n \times n}$ is called the diffusion matrix of the system.

General form of a cross-diffusion system:

 $\partial_t u - \operatorname{div} (A(u) \nabla u) = 0, \quad u(t = 0, \cdot) = u^0 = (u_1^0, \cdots, u_n^0)$

< ロ > < 同 > < 回 > < 回 >

Cross-diffusion systems with entropic structure

 $\partial_t u - \operatorname{div} \left(A(u) \nabla u \right) = 0$

We focus in the talk on a particular type of cross-diffusion systems which satisfy specific properties

• Volumic constraints: $\forall 1 \leq i \leq n$, $u_i(t,x) \geq 0$ and $\sum_{i=1}^n u_i(t,x) = 1$

i.e. $u(t,x) \in \mathcal{A} := \{ u \in \mathbb{R}_+^n : \sum_{i=1}^n u_i = 1 \}.$

Cross-diffusion systems with entropic structure

 $\partial_t u - \operatorname{div} \left(A(u) \nabla u \right) = 0$

We focus in the talk on a particular type of cross-diffusion systems which satisfy specific properties

• Volumic constraints: $\forall 1 \leq i \leq n$, $u_i(t,x) \geq 0$ and $\sum_{i=1}^n u_i(t,x) = 1$

i.e. $u(t,x) \in \mathcal{A} := \{ u \in \mathbb{R}_+^n : \sum_{i=1}^n u_i = 1 \}.$

• Entropic structure

More precisely, we consider here cross-diffusion systems such that there exists an entropy functional which is a Lyapunov function for the system (key ingredient in order to establish the existence of solutions).

In general, such an entropy functional reads as $\mathcal{H}(u) = \int_{\Omega} h(u)$ for some convex function $h : \mathcal{A} \to \mathbb{R}$ such that $D^2 h(u) \mathcal{A}(u)$ is a positive semi-definite matrix

$$\begin{split} \frac{d}{dt}\mathcal{H}(u) &= \frac{d}{dt}\int_{\Omega}h(u) = \int_{\Omega}Dh(u)\cdot\partial_{t}u = -\int_{\Omega}\nabla Dh(u)\cdot A(u)\nabla u \\ &= -\int_{\Omega}\nabla u\cdot D^{2}h(u)A(u)\nabla u \leqslant 0. \end{split}$$

Denoting by $M(u) := A(u)(D^2h(u))^{-1}$ the mobility matrix, then the cross-diffusion system formally reads as

 $\partial_t u - \operatorname{div}(M(u)\nabla Dh(u)) = 0$

and it formally holds that

$$\begin{aligned} \frac{d}{dt}\mathcal{H}(u) &= \frac{d}{dt} \int_{\Omega} h(u) = \int_{\Omega} Dh(u) \cdot \partial_t u = -\int_{\Omega} \nabla Dh(u) \cdot A(u) \nabla u \\ &= -\int_{\Omega} \nabla u \cdot D^2 h(u) A(u) \nabla u \\ &= -\int_{\Omega} \nabla Dh(u) \cdot M(u) \nabla Dh(u) \leqslant 0. \end{aligned}$$

Global existence results obtained using the so-called boundedness by entropy principle, first introduced in [Burger, Di Francesco, Pietschmann, Schlake (2010)], and then further developped in [Jüngel (2015)].

イロト イヨト イヨト イヨト

Example 1: model for the solid phase

Model for solid phase: Cross-diffusion equations formally derived from a stochastic hopping model on a network: for $1 \le i \le n$,

$$\partial_t u_i - \operatorname{div}\left(\sum_{j=1}^n c_{ij}^s \left(u_j \nabla u_i - u_i \nabla u_j\right)\right) = 0$$

for some coefficients $c_{ij}^s = c_{ji}^s > 0$.

$$J_i = \sum_{j=1}^n c_{ij}^s \left(u_j \nabla u_i - u_i \nabla u_j \right) \quad \text{i.e.} \quad J = A_s(u) \nabla u$$

Gradient flow structure: $h(u) = \sum_{i=1}^{n} u_i \log u_i$

Important remarks:

• When $c_{ij}^s = c$ for all $1 \le i \ne j \le n$, the system boils down to a system of decoupled heat equations:

$$\partial_t u_i - c\Delta u_i = 0$$

• $\sum_{i=1}^n J_i = 0$

< ロト < 同ト < ヨト < ヨ)

The Stefan-Maxwell system

The Stefan-Maxwell system reads, together with appropriate initial and no-flux boundary conditions,

$$\partial_t u_i - \operatorname{div} (J_i) = 0,$$

$$\nabla u_i + \sum_{j=1}^n B_{ij}(u) J_j = 0,$$

$$\sum_{i=1}^n J_i = 0$$

where

$$\forall 1 \leq i \neq j \leq n, \quad B_{ij}(u) = -c_{ij}^g u_i, \quad B_{ii}(u) = \sum_{1 \leq j \neq i \leq n} c_{ij}^g u_j$$

with

$$c_{ij}^g=c_{ji}^g>0.$$

Notation: $\langle u, v \rangle := \sum_{i=1}^{n} u_i v_i$ for all $u := (u_i)_{1 \leq i \leq n}, v := (v_i)_{1 \leq i \leq n} \in \mathbb{R}^n$.

Condensed form:

$$\begin{cases} \partial_t u - \operatorname{div} (J) = 0, \\ \nabla u + B(u)J = 0, \\ \langle 1, J \rangle = 0 \end{cases}$$
(2)

ヘロト ヘロト ヘヨト ヘヨト

where $1 = (1, \dots, 1)$.

Giovangigli, 1999; Bothe, 2011; Boudin, Grec, Salvarani, 2012; Jüngel, Steltzer, 2013...

$$\mathcal{A} := \left\{ u := (u_i)_{1 \leq i \leq n} \in \mathbb{R}^n_+, \quad \sum_{i=1}^n u_i = \langle 1, u \rangle = 1 \right\}$$
$$\mathcal{V} := \left\{ v := (v_i)_{1 \leq i \leq n} \in \mathbb{R}^n, \quad \sum_{i=1}^n v_i = \langle 1, v \rangle = 0 \right\}$$

Lemma (Jüngel, Steltzer, 2013)

Let $u \in (\mathbb{R}^*_+)^n \cap \mathcal{A}$. Then, it holds that

Span $B(u) = \mathcal{V}$ and Ker $B(u) = Span\{u\}$.

イロト イヨト イヨト イヨト

Properties of the matrix B(u)

Consequence: Thus, for any $u \in (\mathbb{R}^*_+)^n \cap A$, for any vector $z \in \mathcal{V}$ and any vector $y \in \mathbb{R}^n$ such that $\langle y, u \rangle \neq 0$, there exists a unique solution $x \in \mathbb{R}^n$ solution to

B(u)x = z and $\langle y, x \rangle = 0$.

Assume now that there exists a solution (u, J) to (2) such that $u(t, x) \in (\mathbb{R}^*_+)^n \cap \mathcal{A}$ for almost all t > 0 and $x \in \Omega$. Then, $\nabla u(t, x) \in \mathcal{V}^d$ since

$$\sum_{i=1}^{n} u_i = 1 \text{ a.e. implies that } \sum_{i=1}^{n} \nabla u_i = 0 \text{ a.e.}$$

Besides, $\langle 1, u \rangle = 1 \neq 0$ a.e. Then, a.e., there exists a unique solution $J(t, x) \in \mathbb{R}^{n \times d}$ such that, a.e.

$$\begin{cases} B(u)J + \nabla u = 0\\ \langle 1, J \rangle = 0, \end{cases}$$

and there exists a matrix field $A_g : (\mathbb{R}^*_+)^n \cap \mathcal{A} \to \mathbb{R}^{n \times n}$ such that

 $J = A_g(u)\nabla u.$

Gradient flow structure: $h(u) = \sum_{i=1}^{n} u_i \log u_i$

イロト イヨト イヨト イヨト 二日

Let T > 0 be some final time and $Q_T := (0, T) \times \Omega$.

Definition (Weak solution)

A weak solution (u, J) to the the solid/Stefan-Maxwell system, corresponding to the initial profile $u^0 \in L^{\infty}(\Omega; \mathcal{A})$, with no-flux boundary conditions, is a pair (u, J) such that $u \in L^{\infty}(Q_T; \mathcal{A}) \cap L^2((0, T); H^1(\Omega)^n)$, $\nabla \sqrt{u} \in L^2(Q_T)^{n \times d}$, $J \in L^2(Q_T; \mathcal{V}^d)$ satisfies

 $J = A_s(u)\nabla u$ or $B(u)J + \nabla u = 0$ a.e. in Q_T

and such that for all $\phi := (\phi_i)_{1 \leqslant i \leqslant n} \in \mathcal{C}^{\infty}_{c}([0, T) \times \overline{\Omega})^n$,

$$-\int \int_{Q_T} \langle u, \partial_t \phi \rangle + \int_{\Omega} \langle u^0, \phi(0, \cdot) \rangle + \int \int_{Q_T} \sum_{i=1}^n J_i \cdot \nabla \phi_i = 0.$$

Theorem (Jüngel, Steltzer, 2013, Jüngel, 2015)

There exists at least one weak solution to (2) in the sense of the previous definition.

For both systems,

$$h(u) = \sum_{i=1}^n u_i \log u_i$$

Let $c^* := \min_{1 \leq i \neq j \leq n} c_{ij} > 0$, $\overline{c}_{ij} = c_{ij} - c^* \ge 0$ and $\overline{c} := \max_{1 \leq i \neq j \leq n} \overline{c}_{ij}$.

Then, the following inequality holds for all u solution to the solid/Stefan-Maxell system

$$\frac{d}{dt}\mathcal{H}(u) \leqslant -\frac{1}{2}\alpha \sum_{i=1}^{n} \int_{\Omega} |\nabla \sqrt{u_i}|^2 - \frac{1}{2}c^* \int_{\Omega} |J|^2 \leqslant 0,$$
(3)

with

$$\alpha = \alpha(c^*, \overline{c}) > 0.$$

This inequality enables to obtain bounds on

$$\int\!\int_{Q_T} |\nabla \sqrt{u_i}|^2 \quad \text{ and } \quad \int\!\int_{Q_T} |J|^2$$

イロト イヨト イヨト イヨト

- the non-negativity of the volumic fractions;
- the conservation of mass

$$\int_{\Omega} u_i(t) = \int_{\Omega} u_i^0 = m_i^0, \quad \forall 1 \leq i \leq n.$$

• the preservation of the volume-filling constraint

$$u_i \ge 0$$
 and $\sum_{i=1}^n u_i = 1$ a.e.

• the entropy dissipation relation (3) (or a discrete version of it).

Burger, Cancès, Carillo, Chainais-Hillaret, Daus, Filbet, Guichard, Jüngel, Perugia, Pietschamnn, Schmidtchen...

In the particular case of the Stefan-Maxell system,

- Boudin, Grec, Salvarani, 2012: ternary system, dimension 1
- Jüngel, Leingang, 2019: finite element approximation

Here, we use finite volume schemes based on two-point flux approximation:

- solid phase [Cancès, Gaudeul, 2020]
- Stefan-Maxwell [Cancès, Ehrlacher, Monasse, 2024]

< ロ > < 同 > < 回 > < 回 >

For all $u \in \mathbb{R}^n_+$, it holds that

$$B(u) = c^* \langle 1, u \rangle I + c^* C(u) + \overline{B}(u)$$

where, for all $1 \leq i, j \leq n$,

$$c_{ij}(u) = u_i, \quad \overline{B}_{ii}(u) = \sum_{1 \le i \ne j \le n} \overline{c}_{ij} u_j, \quad \overline{B}_{ij}(u) = -\overline{c}_{ij} u_i \ i \ne j$$

The matrix \overline{B} has the same expression as B except that the coefficients c_{ij} are replaced by \overline{c}_{ij} .

In particular, if $u \in A$, $B(u) = c^*I + c^*C(u) + \overline{B}(u)$. Moreover, for all $J \in \mathcal{V}$, C(u)J = 0. Thus,

$$B(u)J = c^*J + \overline{B}(u)J$$

イロト イロト イヨト イヨー

 \mathcal{T} : set of cells \mathcal{E} : set of faces (or edges) $(x_{\mathcal{K}})_{\mathcal{K}\in\mathcal{T}}$: set of cell centers Assumption: orthogonality property

Let $\Delta t > 0$, $t_p = p\Delta t$ for all $p \in \mathbb{N}$ and $P_T \in \mathbb{N}^*$ such that $t_{P_T} = P_T \Delta = T$.

The numerical method is an iterative scheme, where for all $p \in \mathbb{N}^*$, a discrete solution

$$\boldsymbol{u}^{p} := (\boldsymbol{u}_{i}^{p})_{1 \leqslant i \leqslant n} \in \left(\mathbb{R}^{\mathcal{T}}\right)^{n},$$

so that $\boldsymbol{u}_i^p = \left(u_{i,K}^p\right)_{K\in\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}$ with

 $u_{i,K}^{p}$ an approximation of the function u_{i} at time t_{p} in the cell K,

will be computed given the value of the discrete solution at the previous time step \boldsymbol{u}^{p-1} . Let $\boldsymbol{u}^0 = (\boldsymbol{u}^0_i)_{1 \leq i \leq n} \in (\mathbb{R}^{\mathcal{T}})^n$ be a discretized initial condition.

イロト イヨト イヨト イヨト 二日

Notation

- For all $K \in \mathcal{T}$, $m_K = |K|$ the Lebesgue measure of the cell K;
- For all $\sigma \in \mathcal{E}$, $m_{\sigma} = \mathcal{H}^{d-1}(\sigma)$ the d-1-dimensional Hausdorff measure of the face σ ,

$$d_{\sigma} := \begin{cases} |x_{\mathcal{K}} - x_{\mathcal{L}}| & \text{if } \sigma = \mathcal{K}|\mathcal{L} \text{ is an interior face;} \\ d(x_{\mathcal{K}}, \sigma) & \text{if } \sigma \in \mathcal{E}_{\mathcal{K}} \text{ is an exterior face,} \end{cases}$$

and

$$\tau_{\sigma} = \frac{m_{\sigma}}{d_{\sigma}}$$

Notation

For all $\mathbf{v} = (v_K)_{K \in \mathcal{T}} \in \mathbb{R}^{\mathcal{T}}$, for all $K \in \mathcal{T}$ and all $\sigma \in \mathcal{E}_K$, we denote by $v_{K\sigma}$ the mirror value of v_K across σ , i.e.

$$v_{K\sigma} = \begin{cases} v_L & \text{if } \sigma = K | L \text{ for some } L \in \mathcal{T}, \\ v_K & \text{if } \sigma \text{ is an exterior face,} \end{cases}$$

The oriented jump of \boldsymbol{v} across σ is defined by

$$D_{K\sigma} \mathbf{v} := \mathbf{v}_{K\sigma} - \mathbf{v}_K$$

Finally, $v_{\sigma,\log}$ denotes the logarithmic mean between v_K and $v_{K\sigma}$, i.e.

$$u_{\sigma,\log} := \begin{cases}
0 & \text{if } \min(v_{\mathcal{K}}, v_{\mathcal{K}\sigma}) \leqslant 0, \\
v_{\mathcal{K}} & \text{if } v_{\mathcal{K}} = v_{\mathcal{K}\sigma} \geqslant 0, \\
\frac{v_{\mathcal{K}} - v_{\mathcal{K}\sigma}}{\log(v_{\mathcal{K}}) - \log(v_{\mathcal{K}\sigma})} & \text{otherwise.}
\end{cases}$$

イロト イヨト イヨト イヨト

Numerical scheme

For all $K \in \mathcal{T}$ and all $1 \leq i \leq n$,

$$m_{K} \frac{u_{i,K}^{p} - u_{i,K}^{p-1}}{\Delta t} + \sum_{\sigma \in \mathcal{E}_{K}} m_{\sigma} J_{i,K\sigma}^{p} = 0,$$
(4)

where for all $\sigma \in \mathcal{E}_{K}$, $J_{K\sigma}^{p} = \left(J_{i,K\sigma}^{p}\right)_{1 \leq i \leq n} \in \mathbb{R}^{n}$ is computed as follows:

• if $\sigma = K | L$ is an interior face,

$$\frac{1}{d_{\sigma}}D_{K\sigma}\boldsymbol{u}_{i}^{p}+\boldsymbol{c}^{*}J_{i,K\sigma}^{p}+\sum_{1\leqslant j\leqslant n}\overline{B}_{ij}(\boldsymbol{u}_{\sigma,\log}^{p})J_{j,K\sigma}^{p}=0,\quad\forall 1\leqslant i\leqslant n,$$
(5)

where $u^p_{\sigma,\log} = \left(u^p_{i,\sigma,\log}
ight)_{1\leqslant i\leqslant n}$, and

$$J_{L\sigma} = -J_{K\sigma} \tag{6}$$

• if σ is an exterior face,

$$J^{p}_{K\sigma} = 0.$$
 (7)

・ロト ・四ト ・ヨト ・ヨト
Properties of the scheme

Solid phase: [Cancès, Gaudeul, 2020]

Theorem (Cancès, VE, Monasse, 2024)

Let $(\mathcal{T}, \mathcal{E}, (x_K)_{K \in \mathcal{T}})$ be an admissible mesh of Ω and let \mathbf{u}^0 be an initial condition such that $\mathbf{u}^0 \in \mathcal{A}^{\mathcal{T}}$. Then, for all $p \in \mathbb{N}^*$, the nonlinear system of equations (4)-(5)-(6)-(7) has at least a (strictly) positive solution $\mathbf{u}^p \in \mathcal{A}^{\mathcal{T}}$. This solution satisfies

$$\sum_{K\in\mathcal{T}}u_{i,K}^{p}=\sum_{K\in\mathcal{T}}u_{i,K}^{0}.$$

In addition, the corresponding fluxes $\mathbf{J}^{p} = (J^{p}_{\kappa\sigma})_{\sigma\in\mathcal{E}}$ are uniquely determined by (5)-(6)-(7) and belong to $\mathcal{V}^{\mathcal{E}}$, i.e.

$$\forall K \in \mathcal{T}, \ \forall \sigma \in \mathcal{E}_K, \quad \sum_{i=1}^n J_{i,K\sigma}^p = 0$$

Moreover, the following discrete entropy dissipation estimate holds

$$E_{\mathcal{T}}(\boldsymbol{u}^{p}) + \Delta t \sum_{\sigma = K \mid L \in \mathcal{E}_{int}} \left(\frac{c^{*}}{2} m_{\sigma} d_{\sigma} |J_{K\sigma}^{p}|^{2} + \frac{\alpha}{2} \tau_{\sigma} |D_{K\sigma} \sqrt{\boldsymbol{u}^{p}}|^{2} \right) \leq E_{\mathcal{T}}(\boldsymbol{u}^{p-1})$$

where the discrete entropy functional is defined as

$$E_{\mathcal{T}}(\boldsymbol{u}) = \sum_{K \in \mathcal{T}} \sum_{i=1}^{n} m_{K} u_{i,K} \log(u_{i,K}), \quad \forall \boldsymbol{u} = (\boldsymbol{u}_{i})_{1 \leq i \leq n} \in \mathcal{A}^{\mathcal{T}}.$$

Convergence of the scheme

Let $(\mathcal{T}_m, \mathcal{E}_m, (x_K^m)_{K \in \mathcal{T}_m})_{m \in \mathbb{N}}$ be a sequence of admissible meshes such that $h_{\mathcal{T}_m} := \max_{K \in \mathcal{T}_m} \operatorname{diam}(K) \underset{m \to +\infty}{\longrightarrow} 0$ and

$$\zeta_{\mathcal{T}_m} := \min_{K \in \mathcal{T}_m} \min_{\sigma \in \mathcal{E}_K} \frac{d(x_K, \sigma)}{d_{\sigma}} \ge \eta, \quad \forall m \in \mathbb{N},$$

for some $\eta > 0$ independent of *m*.

Let $(\Delta t_m)_{m\in\mathbb{N}}$ be a sequence of positive time steps such that $\Delta t_m \xrightarrow[m \to +\infty]{} 0$. Solid phase: [Cancès, Gaudeul, 2020]

Theorem (Cancès, VE, Monasse, 2024)

There exist $u \in L^{\infty}(Q_T; \mathcal{A}) \cap L^2((0, T); H^1(\Omega)^n)$ with $\sqrt{u} \in L^2((0, T); H^1(\Omega)^n)$ and $J \in L^2(Q_T, \mathcal{V}^d)$ such that, up to the extraction of a subsequence,

$$\begin{split} & u_{\mathcal{T}_m,\Delta t_m} = (u_{i,\mathcal{T}_m,\Delta t_m})_{1 \leqslant i \leqslant n} \underset{m \to +\infty}{\longrightarrow} u \text{ a.e. in } Q_T, \\ & J_{\mathcal{E}_m,\Delta t_m} = (J_{i,\mathcal{E}_m,\Delta t_m})_{1 \leqslant i \leqslant n} \underset{m \to +\infty}{\longrightarrow} J \text{ weakly in } L^2(Q_T)^{n \times d} \end{split}$$

Besides, (u, J) is a weak solution of the Stefan-Maxwell problem.

 M_s, M_g are positive semi-definite mobility matrices.

Reformulation of the Butler-Volmer fluxes: for $i \in \{1, ..., n\}$,

$$F_i = u_i^s \exp\left(\frac{1}{2} \llbracket \mu_i^* \rrbracket\right) - u_i^g \exp\left(-\frac{1}{2} \llbracket \mu_i^* \rrbracket\right) = 2\sqrt{u_i^s u_i^g} \sinh\left(-\frac{1}{2} \llbracket \mu_i(t) \rrbracket\right),$$

which guarantees that $F(t)^T \llbracket \mu(t) \rrbracket \leq 0$.

イロン イロン イヨン イヨン

Reformulation of the Butler-Volmer fluxes: for $i \in \{1, \ldots, n\}$,

$$F_i = u_i^s \exp\left(\frac{1}{2} \llbracket \mu_i^* \rrbracket\right) - u_i^g \exp\left(-\frac{1}{2} \llbracket \mu_i^* \rrbracket\right) = 2\sqrt{u_i^s u_i^g} \sinh\left(-\frac{1}{2} \llbracket \mu_i(t) \rrbracket\right),$$

which guarantees that $F(t)^T \llbracket \mu(t) \rrbracket \leq 0$. Therefore, the free energy is a Lyapunov functional:

 $\frac{d}{dt}\mathcal{H}(u(t),X(t))\leqslant 0.$

Reformulation of the Butler-Volmer fluxes: for $i \in \{1, \ldots, n\}$,

$$F_i = u_i^s \exp\left(\frac{1}{2} \llbracket \mu_i^* \rrbracket\right) - u_i^g \exp\left(-\frac{1}{2} \llbracket \mu_i^* \rrbracket\right) = 2\sqrt{u_i^s u_i^g} \sinh\left(-\frac{1}{2} \llbracket \mu_i(t) \rrbracket\right),$$

which guarantees that $F(t)^T \llbracket \mu(t) \rrbracket \leq 0$. Therefore, the free energy is a Lyapunov functional:

 $\frac{d}{dt}\mathcal{H}(u(t),X(t)) \leq 0.$

Stationary solutions $(\overline{u}, \overline{X})$ must be constant in each connected part of $\overline{\Omega} := (0, \overline{X}) \cup (\overline{X}, 1)$.

Proposition (Stationary states)

In addition to the trivial pure phase solutions, there exists a non-trivial stationary solution $(\overline{u}^s, \overline{u}^g, \overline{X}) \in \mathcal{A} \times \mathcal{A} \times (0, 1)$ if and only if

$$\min\left(\sum_{i=1}^{n} m_{i}^{0} \exp\left(\left[\left[\mu_{i}^{*}\right]\right]\right), \sum_{i=1}^{n} m_{i}^{0} \exp\left(-\left[\left[\mu_{i}^{*}\right]\right]\right)\right) > 1$$

Moreover, under the latter assumption, this stationary state is unique.

discretized on a uniform mesh of N = 100 cells.

• Long-time asymptotics: relative free energy $\mathcal{H}^{p}(\boldsymbol{u}_{\Delta x}^{p}, X^{p}) - \mathcal{H}^{\infty}(\boldsymbol{u}^{\infty}, X^{\infty})$ and relative interface $|X^{\infty} - X^{p}|$ over time.

Convergence of the scheme

Figure: Convergence analysis of the solution under space grid refinement

Loss of order: first-order accurate on the concentrations in the case of a moving interface, second-order in fixed domains.

• • • • • • • • • • •

• Proving convergence of the scheme to an appropriate notion of weak solution, providing existence of global solutions to the model.

< □ > < □ > < □ > < □ > < □ >

- Proving convergence of the scheme to an appropriate notion of weak solution, providing existence of global solutions to the model.
- Long-time behaviour. Conjecture: under the equilibrium condition, the non-trivial stationary state is the only stable one and weak solutions converge exponentially fast to it for close enough initial conditions.

Formal (1d) derivation of the model for the cross-diffusion equations inside the solid

Let $\Delta t > 0$. Let $p_{ij} = p_{ji}$ represent the probability that an atom of type *i* exchange its position in the solid with an atom of type *j*.

Assume for the moment that d = 1, $\Omega = (0, e_0)$ with $e_0 > 0$ and let us introduce a uniform discretization grid $(x_k)_{0 \le k \le N}$ of $(0, e_0)$ defined by $x_k = k\Delta x$ with $\Delta x = \frac{e_0}{N}$ for $N \in \mathbb{N}^*$.

Let us denote by $u_i^k(t)$ the local concentration of atom *i* in the k^{th} cell (x_{k-1}, x_k) .

$$\begin{split} & u_i^k(t + \Delta t) - u_i^k(t) \\ &\approx \sum_{0 \le j \le n, \ j \ne i} p_{ij}[u_j^k(t)u_i^{k+1}(t) + u_j^k(t)u_i^{k-1}(t) - u_j^{k-1}(t)u_i^k(t) + u_j^{k+1}(t)u_i^k(t)] \\ &\approx \sum_{0 \le j \le n, \ j \ne i} p_{ij}[u_j^k(t)(u_i^{k+1}(t) + u_i^{k-1}(t) - 2u_i^k(t)) - u_i^k(t)(u_j^{k-1} + u_j^{k+1}(t) - 2u_j^k(t))] \end{split}$$

イロト イヨト イヨト イヨト

Taking now (for instance) the scaling $\Delta t = 2Q\Delta x^2$ for some constant Q > 0 and denoting by $c_{ii}^s := \frac{p_{ij}}{Q}$, we obtain the limit equation

$$\partial_t u_i = \sum_{0 \le j \le n, \ j \ne i} c_{ij}^{s} (u_j \partial_{xx} u_i - u_i \partial_{xx} u_j)$$
$$= \partial_x \left[\sum_{0 \le j \le n, \ j \ne i} c_{ij}^{s} (u_j \partial_x u_i - u_i \partial_x u_j) \right]$$

Remark: Rigorous hydrodynamic limit of multi-species symmetric exclusion systems [Quastel, 91], [Erignoux, 2018], [Dabaghi, VE, Strössner, 2018]
